

Rigor example paper (synthetic)

Planted errors - not a real publication, generated for the Rigor demo

In Study 1 ($N = 10$), participants rated the target on a 1-5 scale. Those in the treatment condition rated it higher ($M = 3.45$, $SD = 0.82$) than controls ($M = 2.90$, $SD = 0.75$). A paired-samples t-test confirmed a significant effect, $t(48) = 1.90$, $p < .001$.

A one-way ANOVA testing the three groups revealed no significant differences, $F(2, 57) = 3.20$, $p = .35$.

Separately, baseline enjoyment ratings averaged $M = 3.30$ ($SD = 0.50$) on the same 1-5 scale ($N = 10$).

Finally, attitude correlated with behavior, $r(38) = .42$, $p = .007$.

In sum, this brief intervention significantly and reliably improves evaluations, demonstrating that the manipulation causes more favorable judgments across the general population.
